

# CHALLENGES FOR FRONT END DEVELOPERS OF LARGE WEB APPLICATIONS

Graham Hinchly  
*FT Labs*

Me

[app.ft.com](http://app.ft.com)

Some things on the web  
are hard

When you have a large  
amount of code they get  
really hard

But why is it harder on  
the web than elsewhere?

Languages lack  
encapsulation

Browser rendering model  
designed for documents

Sorry NO  
INTERNET Today

Built around assumption of **always**  
**on, stable internet connection**

How do we deal with  
this?

Scream in the street for a bit. YMMV.

**Modularisation**

**Performance**

**Offline**

# Modularisation

Encapsulation, managing dependencies and using components

Encapsulation is our  
friend

# CommonJS Spec

- Declare dependencies at the top of the file with `require`
- Expose public API via `exports`
- Not supported by the browser 😞

```
// Declare dependencies
var depA = require("depA");
var depB = require("../depB");
```

```
/**
Module code
**/
```

```
// Export public API
exports.foo = foo;
```

Allows you to write  
JavaScript like this

But what if I want to use bits  
of other peoples' code...

Cleanly manages your  
JavaScript dependencies

# npm + browserify

- Install from npm registry
- ...or specify git URL
- Great for breaking up a monolith

```
$ npm install fastclick --save
```

package.json 

```
{  
  "name": "ft-app",  
  "dependencies": {  
    "fastclick": "^1.0.3",  
    [...]  
  }  
}
```

someModule.js 

```
var fc = require("fastclick");  
/**  
Module code  
**/
```

# It's not perfect (yet...)

- Git tags don't guarantee repeatability
  - Use npm-shrinkwrap
- Registry introduces a single point of failure
  - We use a private lazy cache

CSS isn't encapsulated  
either...

# Leak-proof styling for reusable components

- Context agnostic
- Non-semantic naming – clear that it's reusable
- Classes prefixed with component name

Code example from [smashingmagazine.com/2013/05/23/building-the-new-financial-times-web-app-a-case-study/](https://smashingmagazine.com/2013/05/23/building-the-new-financial-times-web-app-a-case-study/)

```
<div class="apple">
  <h2 class="apple_headline">...
  <h3 class="apple_subhead">...
  <div class="apple_body">...
</div>
```

```
.apple {}
.apple_headline {
  font-size: 40px;
}
.apple_subhead {
  font-size: 20px;
}
.apple_body {
  font-size: 14px;
  column-count: 2;
  color: #333
}
```

Works for one app – what about sharing components across an entire organisation?

Developer guide

Third party component A List

Origami is about empowering developers of **all levels** to build **robust, on-brand** products ranging from simple static sites through to rich, dynamic web applications, to do it **faster**, to do it **cheaper**, and leave them more **supportable** and more **maintainable**.

# origami.ft.com

The future – fully  
encapsulated web  
components?

# Performance

Maintaining smooth animations and a responsive UI

# Perils of a single thread

Long running processes block user  
interactions

# Perils of a single thread

Missed frames make animations, scrolling and swiping feel “janky”

Synchronous tasks also  
block screen updates

6 frames per second

*Great* for animated gifs

*Rubbish* for your app

# Consistent frame rate

We want something that's silky smooth, so we aim for 60 frames per second. This gives us just **16.6ms between frames**

# What happens on this thread?

JavaScript execution

Layout

Style recalculation

Paint

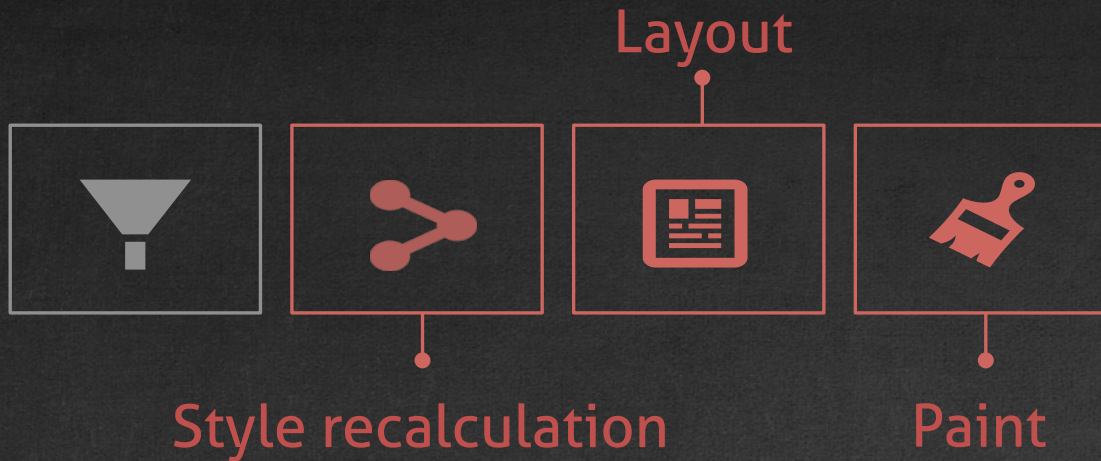

JavaScript execution

JavaScript execution is rarely the bottleneck

Which means we need to understand the other operations taking place (sorry!)

# Style recalculation

Working out what things should look like from CSS & DOM

# Layout

Working out what goes where on the screen

# Paint

Putting the pixels onto the screen\*

\* Technically this is the browser painting to a bitmap and then uploading to the GPU rather than putting pixels directly on the screen

# Use animation effects which avoid layout/paint

- transforms:
  - translate
  - scale
  - rotation
- opacity
- These use the GPU, which is optimised for just such a task

```
// Position/margin slow
style.top = x;
style.marginLeft = x;
```

```
// translate & translate3d fast
style[transform] =
"translate(" + x + "px," + x +
"px)";
```

```
/** may need to use "translateZ
hack" to manually force layer
creation */
style[transform] =
"translateZ(0)"
```

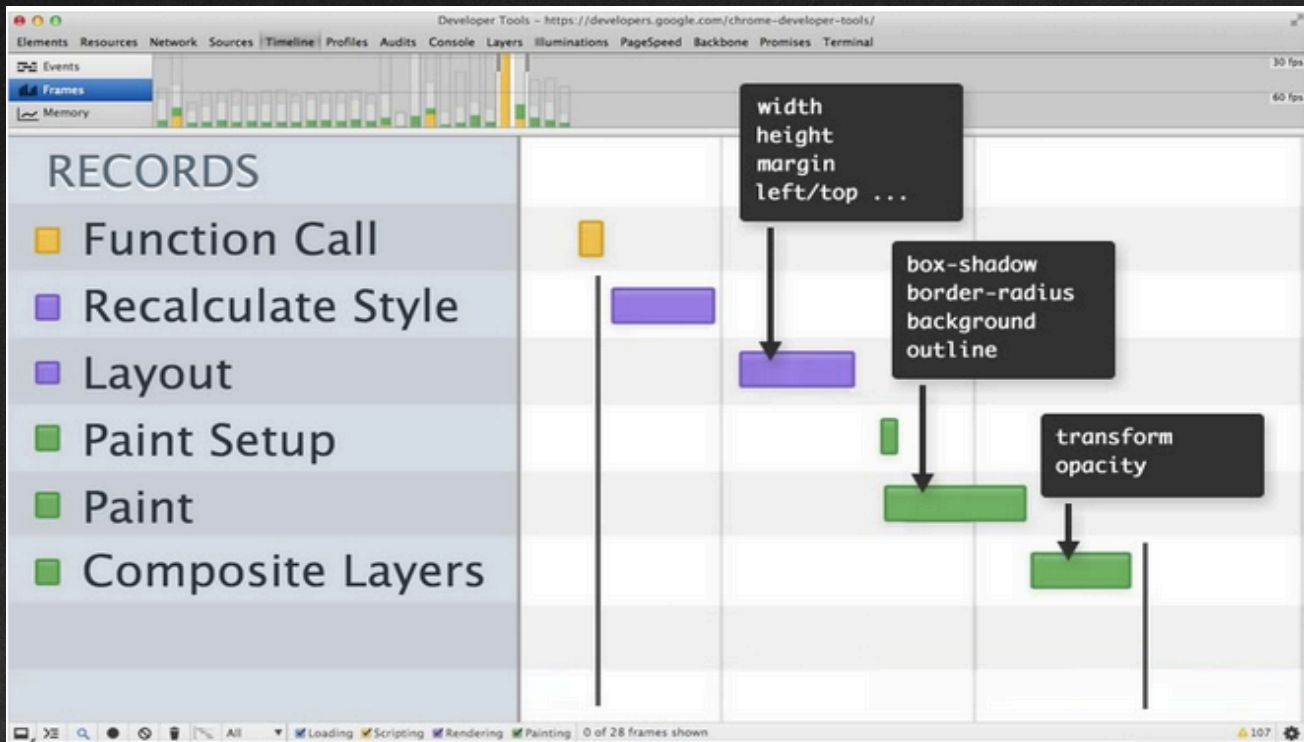

If you can't eliminate,  
**reduce time** spent doing  
these tasks

# Time for some detective work...

# Timeline – shows us time spent in JS execution, layout and paint

Timeline “frames view” shows amount of work required to render each frame

Taller bars = slower

We want all our frames **below** the 60 FPS line

# Let's see how much time the entire page would take to paint...

The image shows a web application interface with a sidebar menu on the left and a main content area on the right. The sidebar menu includes the following items:

- Home page
- World
- Companies
- Markets
- Lex
- Comment & Analysis
- Leaders & Letters
- Business Life
- Business Education

The main content area displays a news article titled "Survival in Brazil". Overlaid on the right side of the image is the Chrome DevTools Performance panel, which shows the "Page paint time (ms)" for the current page. The panel displays a green bar representing the paint time, with the following values:

- Page paint time (ms): 21.2 (16.3-27.6)
- GPU memory: 32.5 MB used, 512.0 MB max

The DevTools panel also includes a "Rendering" tab with the following settings:

- ☐ Show paint rectangles
- ☐ Show composited layer borders
- ☒ Show FPS meter
- ☒ Enable continuous page repainting
- ☐ Show potential scroll bottlenecks

# Keep your painting simple...

- Hide elements to see what impact they make on page paint time
- Common suspects: lots of box-shadow and border-radius

# Reducing relayout

Writing to the DOM **invalidates** previous calculations

Reading a geometric value from the DOM once it has been invalidated **forces a relayout**

# Reducing layout

Doing this repeatedly prevents the browser from being able to render a frame, resulting in **dropped frames**

# Batch DOM read/writes

Instead we can queue these reads and writes together, and execute them **once per frame**

This can be hard to do manually,  
especially with lots of components, but  
we can manage it with a library:

wilsonpage/fastdom

Putting it all together:  
Swiping on app.ft.com

# Offline

Client-side storage options and their limitations

# Client Side Storage Options

Cookies

AppCache (flawed, but usable)

LocalStorage (fast, but synchronous)

IndexedDB (async, but tricky to use)

# AppCache ☹️

Cookies

AppCache

LocalStorage

IndexedDB

- Well intentioned, but flawed
- However, it *is* usable
  - We use it for bare minimum:  
bootstrap code, fonts, splash screen  
images

# LocalStorage 😐

- Simple API
- Fast...?

Cookies

AppCache

LocalStorage

IndexedDB

# Faster than cache...

Cookies

AppCache

LocalStorage

IndexedDB

<http://www.mobify.com/blog/smartphone-localstorage-outperforms-browser-cache/>

# LocalStorage

Cookies

AppCache

LocalStorage

IndexedDB

- But:
  - Limited storage
  - Synchronous
    - File I/O for persistence means it can have variable performance
  - Odd behaviour in Safari private browsing
  - We use a lightweight wrapper called Superstore by Matt Andrews

# IndexedDB 🙄

Cookies

AppCache

LocalStorage

IndexedDB

- Async key value object store
  - We use this for articles and images
- Not supported everywhere - use polyfill<sup>[1]</sup> to support (long deprecated) WebSQL
- Managing versions and migrations can be awkward
- Documentation is variable

[1] <http://nparashuram.com/IndexedDBShim/> or <https://github.com/mozilla/localForage>

# Future: ServiceWorker 🤖

- Sits in the middle of browser and network
- Lots of good things:
  - Extensible w/ low level, granular control
  - “Cache API” for storage
  - Async
- But:
  - No access to localStorage
  - HTTPS only

- Using ServiceWorker today:  
[jakearchibald.com/2014/using-serviceworker-today/](http://jakearchibald.com/2014/using-serviceworker-today/)

# Summary

# A quick recap....

- Modularisation
  - npm + browserify works well for managing client side JS dependencies
  - Prefixed class names for CSS component elements
- Performance
  - Good tools, profile your own use case. Look out for relayout and paint as bottlenecks – batch DOM read/writes and stick to known fast animations
- Offline
  - Hard with limited options, prefer async IndexedDB, look out for ServiceWorker

# Thanks! 😊
